

Features

- Compliant to LIN 2.0, LIN 2.1, LIN 2.2, LIN 2.2A, and ISO 17987-4 Electrical Physical Layer (EPL) Specification
- Compliant to SAE J2602 LIN Network for Vehicle Applications
- Support LIN Data Rates up to 20 Kbps
- Support Wide V_{BAT} Input Voltage Range: 4.5 V to 40 V
- Low-current Standby Mode and Sleep Mode with Bus and Local Wake-up Capability
- Input Levels Compatible with 3.3-V and 5-V MCU Interface
- $\pm 2\%$ Accuracy 5-V or 3.3-V Voltage Regulator with up to 125-mA (DFN, ESOP) Capability
- Ideal Passive Behavior to LIN Bus when Unpowered
- Integrated Pull-up Resistor for LIN Slave Applications
- Protection Feature :
 - IEC 61000-4-2 ESD Protection up to ± 15 kV
 - Bus Fault Protection: ± 45 V
 - V_{BAT} and V_{CC} Undervoltage Protection
 - Voltage Regulator Short to Ground Protection
 - TXD Dominant Time-out Function
 - Thermal Shutdown Protection
- Available in SOP8 Package, ESOP8 Package, and Leadless DFN3X3-8 Package with Improved Automated Optical Inspection (AOI) Capability
- AEC-Q100 Qualified for Automotive Applications, Grade 1

Applications

- Automotive and Transportation
- Body Electronics / Lighting
- Power Train / Chassis
- Infotainment / Cluster
- ADAS / Safety

Description

The TPT1028xQ is a local interconnect network (LIN) system basis chip (SBC), which includes a LIN transceiver, compliant to the ISO 17987-4, SAE J2602 and LIN 2.0, LIN 2.1, LIN 2.2, and LIN 2.2-A physical layer standard, and an integrated low drop out (LDO) voltage regulator. LIN is a low-speed Universal Asynchronous Receiver Transmitter (UART) communication protocol that supports automotive in-vehicle sub-networks.

The LIN SBC is designed in LIN networks up to 20 Kbps and reduces system complexity by providing a 5-V or 3.3-V LDO to power microprocessors, sensors, and other devices. The device supports Sleep mode, in which the LDO and LIN transceivers are shut down while still able to be woken up via the LIN bus. The device integrates a pull high resistor for LIN slave applications and ESD protection, which allows applications to operate with a reduced dependence on external components. With an optimized circuit design, the TPT1028xQ exhibits very low electromagnetic emission (EME) and high electromagnetic immunity (EMI) capabilities.

As designed, the device features overvoltage and loss of ground protection from -45 V to $+45$ V, over-temperature shutdown, under voltage and short to ground protections, and other protection features to enhance the device and network robustness.

The TPT1028xQ is available in SOP-8, ESOP-8, and DFN3X3-8 packages and is AEC-Q100 qualified for automotive applications.

Detailed Description

Overview

The TPT1028xQ is a local interconnect network (LIN) system basis chip (SBC), which includes a LIN transceiver, compliant to the ISO 17987-4, SAE J2602 and LIN 2.0, LIN 2.1, LIN 2.2, and LIN 2.2-A physical layer standard, and an integrated low drop out (LDO) voltage regulator. LIN is a low-speed Universal Asynchronous Receiver Transmitter (UART) communication protocol that supports automotive in-vehicle sub-networks. The LIN SBC is designed in LIN networks up to 20 Kbps and reduces system complexity by providing a 5-V or 3.3-V LDO to power the microprocessors, sensors, and other devices. The device supports Sleep mode, in which the LDO and LIN transceivers are shut down while still able to be waken-up via the LIN bus. The device integrates a pull high resistor for LIN slave applications and ESD protection which allows applications to operate with a reduced dependence on external components. With an optimized circuit design, the TPT1028xQ exhibits very low electromagnetic emission (EME) and high electromagnetic immunity (EMI) capabilities. As designed, the device features overvoltage and loss of ground protection from -45 V to $+45\text{ V}$, over-temperature shutdown, under voltage and short to ground protection, and other protection features to enhance the device and network robustness. The TPT1028xQ is available in SOP-8, ESOP-8, and DFN3X3-8 packages and is AEC-Q100 qualified for automotive applications.

Functional Block Diagram

Figure 4. Functional Block Diagram

Feature Description

Device Operating Modes

The TPT1028xQ supports modes for Normal mode, Power-on mode, Standby mode, and Sleep mode. The figure below shows the state diagram.

Automotive Fault Protected 125mA LIN System Basis Chip (SBC)

Figure 5. Functional Block Diagram

1. The LIN transmitter is enabled in Normal mode when EN and RST_N are high. If EN and/or RST_N go low, the LIN transmitter is disabled. The device can be remotely woken-up via the LIN bus.
2. Until V_{CC} drops below 2 V.
3. The device switches to Standby mode without initiating a reset if a wake-up event and a go-to-sleep event occur simultaneously.

Table 2. Function Table

Mode	EN	RXD	RST_N	Transmitter	LIN BUS Termination
Normal	High	High: recessive state Low: dominant state	V_{CC}	Normal	30 kΩ
Sleep	Low	Floating	GND	Off	Weak current pull-up
Standby	Low	Low (Remote wake-up)	V_{CC}	Off	30 kΩ
		High			
Off	/	Floating	GND	Off	Weak current pull-up

Off Mode

The device switches to Off mode if the battery supply voltage drops below the under-voltage protection threshold or the junction temperature exceeds the overtemperature protection activation threshold.

The LDO and LIN transceiver are disabled in Off mode, the RST_N pin keeps low.

Normal Mode

The device switches to Normal mode from Standby mode or Sleep mode if the EN pin is pulled high.

In Normal mode, the LDO is enabled, and the LIN transceiver can transmit and receive data through the LIN bus line. The receiver detects the data stream at the LIN bus input pin and transfers it to the microcontroller via the RXD pin. On the bus,

Automotive Fault Protected 125mA LIN System Basis Chip (SBC)

a HIGH level corresponds to a recessive state, while a LOW level represents a dominant state. The receiver incorporates a voltage-dependent threshold with hysteresis and an integrated filter to suppress noise on the bus.

The transmit data stream from the protocol controller at the TXD input is converted by the transmitter into a bus signal with an optimized slew rate and wave shaping, aiming to minimize electromagnetic emissions (EME). The LIN bus output pin is pulled HIGH through an internal slave termination resistor. For master applications, an external resistor in series with a diode should be connected between pin VBAT and pin LIN.

Standby Mode

Standby mode is a low-power mode for power-saving applications. The device switches to Standby mode from Off mode if the battery supply voltage rises above the power-on detection threshold.

The device switches to Standby mode from Normal mode if pin TXD is high and pin EN is low during the mode select window.

Standby mode is automatically activated whenever wake-up occurs while the device is in Sleep mode. The remote wake-up event is indicated by a low level on the RXD pin, which can serve as an interrupt for the microcontroller.

The LDO is enabled in Standby mode, and the LIN transceiver is disabled and is capable of being remote wake-up. The wake-up source is indicated by the level on RXD.

Sleep Mode

The Sleep mode offers an extremely low power mode that guarantees extremely low current consumption.

The device switches to Sleep mode from Normal mode if pin TXD and pin EN are both low during the mode select window. The LDO and LIN transceiver are disabled in Sleep mode and pin RST_N is forced low. The device is capable of being remote wake-up via the LIN bus. Input filters are incorporated at the receiver to prevent undesired wake-up events caused by automotive transients or electromagnetic interference (EMI).

Wake-up

A remote wake-up event triggers a transition to Standby mode from Sleep mode.

Remote wake-up through the LIN bus by transmitting a dominant bus state that is sustained for a duration of at least $t_{WAKE_DOM_LIN}$, then followed by a rising edge.

Power Supply

Battery Supply Input

The battery supply, V_{BAT} pin, operating range is from 5.5 V to 40 V, the maximum voltage device can handle is 45 V. If the V_{BAT} input voltage drops below V_{TH_DET_POFF}, the device switches to Off mode, the LDO and LIN transceiver is disabled. The device exits Off mode as soon as the battery supply voltage rises above the V_{TH_DET_PON}. An external diode is needed in series to protect the device against negative voltage.

Voltage Regulator Output

The device integrated a low-dropout voltage regulator supplied via V_{BAT} pin, the V_{CC} output current up to 100 mA. There are two output voltage versions for different power supply voltage microcontroller: the TPT10285 output voltage is 5 V, and the TPT10283 output voltage is 3.3 V.

Reset

The VCC voltage is monitored continuously; if VCC drops below V_{UV} for t_{DET_UV_VCC}, an undervoltage event is detected, and the RST_N pin sets low. When VCC exceeds the undervoltage recovery threshold V_{UVR} for T_{RST}, the RST_N pin goes back to high again.

Protection Features

TXD Dominant Time-out

The device detects TXD dominant time-out and prevents a permanent low on the TXD pin driving the LIN bus into permanent dominant blocking the LIN bus network. If the TXD remains low for longer than t_{TXD_DTO} , the transmitter is disabled until the fault flag has been cleared.

Under-voltage Lockout (UVLO)

The device integrates under-voltage detection and lockout circuit of the supply terminal to keep the device in protected mode if the supply voltage drops below the threshold until the supply voltage is higher than the UVLO threshold. This protects the device and system during undervoltage events on supply terminals.

Over-Temperature Protection (OTP)

The device is protected against over-temperature conditions. If the virtual junction temperature exceeds the shutdown junction temperature T_{J_SD} , the device switches to Off mode. The voltage regulator and the LIN transmitter is switched off, and the pin RST_N is driven low. When the virtual junction temperature falls below $T_{J_SD_R}$, the device switches to normal mode.

Fail-safe Features

An internal pull-down to GND on the TXD pin to establish a predetermined level in case the TXD pin is disconnected.

RXD pin is set floating when the VBAT pin is unpowered.

The LIN transmitter is disabled when either EN or RST_N is low

LIN transmitter is only enabled if a recessive level is present on pin TXD after switching to Normal mode.

The current limit is applied to the LIN transmitter output to protect the LIN bus short circuits to VBAT or GND.

VBAT and GND loss does not impact the LIN bus or the MCU. No reverse current flows from the bus into the LIN pin. The internal integrated LIN slave termination resistor keeps the current path from VBAT to LIN. Disconnecting the LIN transceiver from the power supply does not affect the LIN bus.

Application and Implementation

Note

Information in the following application sections is not part of the 3PEAK's component specification and 3PEAK does not warrant its accuracy or completeness. 3PEAK's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

Typical Application

Figure 6. Typical Application Circuit
